

XAPP979 (v1.0) February 26, 2007

Reference System: OPB IIC Using the ML403 Evaluation Platform

Author: Paul Glover, Ed Meinelt, Lester Sanders

Summary

This application note describes how to build a reference system for the On-Chip Peripheral Bus Inter IC (OPB IIC) core using the IBM PowerPC™ 405 Processor (PPC405) based embedded system in the ML403 Embedded Development Platform. The reference system is Base System Builder (BSB) based.

An IIC primer is given and an OPB IIC register reference is provided. The Xilinx Microprocessor Debugger (XMD) commands are used for verifying that the OPB IIC core operates correctly. Several software projects illustrate how to configure the OPB IIC core, set up interrupts, and do read and write operations. Some of the software projects interface the OPB IIC to the MicroChip 24LC04B serial EEPROM with an IIC interface, while others interface to the TotalPhase Aardvark Adapter, which provides IIC master and slave functionality. The procedure for using ChipScope™ to analyze OPB IIC functionality is provided. The steps used to build a Linux kernel using MontaVista are listed. Simulation output files for analyzing basic IIC transactions are provided.

Included Systems

This application note includes one reference system:

www.xilinx.com/bvdocs/appnotes/xapp979.zip

The project name used in xapp979.zip is ml403_ppc_opb_iic.

Required Hardware/Tools

Users must have the following tools, cables, peripherals, and licenses available and installed:

- Xilinx EDK 8.2.02i
- Xilinx ISE 8.2.03
- Xilinx Download Cable (Platform Cable USB or Parallel Cable IV)
- Monta Vista Linux v2.4 Development Kit
- Modeltech ModelSim v6.1d
- ChipScope v8.2

Introduction

This application note accompanies a reference system built on the ML403 development board. [Figure 1](#) is a block diagram of the reference system.

Figure 1: OPB IIC Reference System Block Diagram

The system uses the embedded PowerPC (PPC) as the microprocessor and the OPB IIC core.

IIC Primer

[Figure 2](#) shows components on an IIC bus. Two IIC masters and three IIC slaves are shown. The master is responsible for setting up transactions. This includes generating the clock on SCL and defining which slave is involved in the communication, with an address field, and which component is transmitting and which component is receiving. Some components are slave only, while others can transition between master and slave operation.

Figure 2: IIC Bus

[Figure 3](#) shows the START and STOP conditions. A START condition is a falling edge on SDA when SCL is high. A STOP condition is a rising edge on SDA when SCL is high. During data transfer, the data line is stable on SDA when SCL is high. Data transitions on SDA when SCL is low. Note that the START and STOP conditions are special conditions, violating the rule that data cannot transition while SCL is high.

Figure 3: Start and Stop Conditions

Figure 4 shows the format of the data transfer of two bytes on the IIC bus, beginning with the START (S) condition and ending with the STOP (P) condition, bounded by an idle IIC (F) bus. After a START condition, an eight bit field is transmitted containing a 7 bit address and a single Read/Write (R/W) bit. This 8 bit address/direction field is followed by an Acknowledge bit. After the address/data field, an eight bit data field is followed by an acknowledge bit (A). The last 8-bit data field is followed by a not acknowledge bit (\bar{A}). This is followed by the STOP condition (P).

A single message can contain multiple start conditions, or a repeated start, without intervening STOP conditions.

In this data transfer, there are two acknowledge bits and one Not Acknowledge on the IIC bus. The distinction between a Not Acknowledge and a No Acknowledge is that Not Acknowledge occurs after a master has read a byte from a slave and a No Acknowledge occurs after a master has written a byte to a slave.

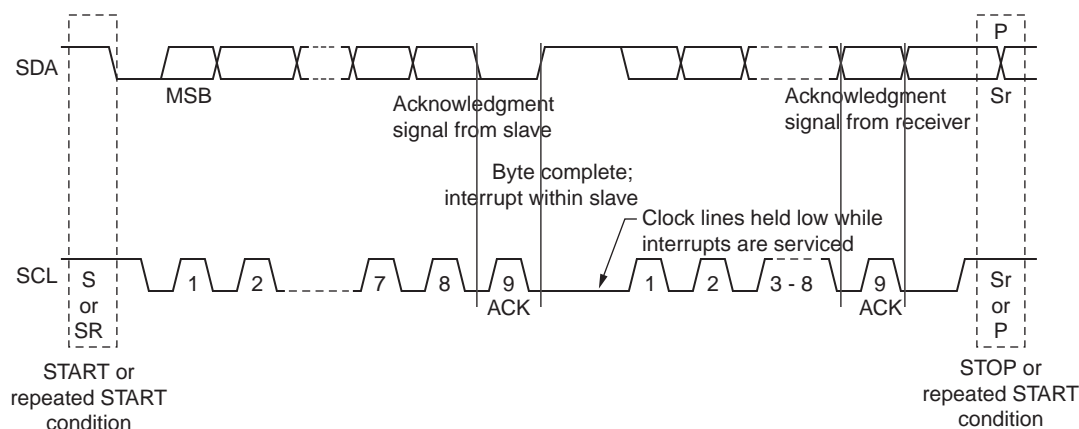

A synchronized SCL is generated with its LOW period determined by the device with the longest low period and its HIGH period determined by the device with the shortest HIGH period.

X979_04_012907

Figure 4: Data Transfer on the IIC Bus

Figure 5 shows the data transfer on the IIC bus, beginning with the START condition and ending with the STOP condition.

X979_05_022307

Figure 5: Generic Data Transfer on the IIC Bus

Figure 6 shows the acknowledge bit on the IIC bus.

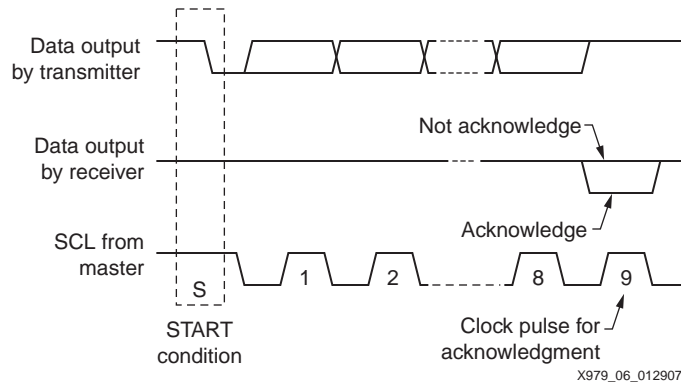

Figure 6: Acknowledge on the IIC Bus

Figure 7 shows bus arbitration of two masters. The IIC bus is a multi-master bus. Masters monitor the IIC bus to determine if the bus is active. The bus is inactive when SCL and SDA are high for a bus free period tBUF of 1.3 us (FAST) or 4.7 us (STD). If two or more masters monitoring the IIC bus determine that the bus is free and begin a bus transaction simultaneously, the IIC bus is arbitrated to determine which master owns the bus. The IIC is a wired AND bus. This means that the bus is HIGH unless any component is driving it LOW.

Masters monitor the bus even after they have started a transaction as the master. If a master is not driving the IIC bus low and the bus is low, the master knows that another master is driving the IIC bus. If a master cannot get the SDA or SCL to go high it loses arbitration. When a master loses arbitration, it stops transmission. The master driving the bus with the last low when the other master(s) drives high becomes the master of the bus.

Figure 7: Arbitration of two Masters

Reference System Specifics

In addition to the PowerPC405 processor and OPB IIC, this system includes DDR and BRAM memory on the PLB, and a UART and interrupt controller on the OPB. Figure 1 provides the block diagram. Table 1 provides the address map of the ML403 XC4VFX12. This is in the system.mhs.

ML403 XC4VFX12 Address Map

Table 1: ML403 XC4VFX12 System Address Map

Peripheral	Instance	Base Address	High Address
PLB_DDR	DDR_SDRAM_32Mx64	0x00000000	0x03FFFFFF
OPB UART16550	RS232_Uart_1	0x40400000	0x4040FFFF
OPB INTC	opb_intc_0	0x41200000	0x4120FFFF
PLB BRAM	plb_bram_if_cntlr_0	0xFFFF8000	0xFFFFFFFF
OPB IIC	IIC_EEPROM	0x40800000	0x4080FFFF

OPB IIC Registers

Table 2 provides the register map for the OPB IIC core.

Table 2: OPB IIC Registers

Register	Address
Device Global Interrupt Enable	C_BASEADDR + 0x01C
Interrupt Status Register	C_BASEADDR + 0x020
Interrupt Enable Register	C_BASEADDR + 0x028
Software Reset Register	C_BASEADDR + 0x040
Control Register	C_BASEADDR + 0x100
Status Register	C_BASEADDR + 0x104
Transmit FIFO	C_BASEADDR + 0x108
Receive FIFO	C_BASEADDR + 0x10C
Slave Address Register	C_BASEADDR + 0x110
Transmit FIFO Occupancy	C_BASEADDR + 0x114
Receive FIFO Occupancy	C_BASEADDR + 0x118
Ten Bit Slave Address Register	C_BASEADDR + 0x11C
Receive FIFO Programmable Depth Interrupt Register	C_BASEADDR + 0x120
General Purpose Output	C_BASEADDR + 0x124

Table 3 provides a description of the OPB IIC control register.

Table 3: OPB IIC Control Register

Bit(s)	Name	Description
0- 24	Reserved	Reserved.
25	GC_EN	General Call Enable. Setting this bit High allows the OPB IIC to respond to a general call address.
26	RSTA	Repeated Start. Writing a “1” to this bit generates a repeated START condition on the bus if the OPB IIC Bus Interface is the current bus Master. Attempting a repeated START at the wrong time, if the bus is owned by another Master, results in a loss of arbitration. This bit is reset when the repeated start occurs. This bit must be set prior to writing the new address to the Tx FIFO or DTR.

Table 3: OPB IIC Control Register (Contd)

Bit(s)	Name	Description
27	TXAK	Transmit Acknowledge Enable. This bit specifies the value driven onto the SDA line during acknowledge cycles for both Master and Slave receivers. Because Master receivers indicate the end of data reception by not acknowledging the last byte of the transfer, this bit is used to end a Master receiver transfer. As a slave, this bit must be set prior to receiving the byte to no acknowledge.
28	TX	Transmit/Receive Mode Select. This bit selects the direction of Master/Slave transfers. This bit does not control the Read/Write bit that is sent on the bus with the address. The Read/Write bit that is sent with an address must be the LSB of the address written into the transmit FIFO.
29	MSMS	Master/Slave Mode Select. When this bit is changed from 0 to 1, the OPB IIC Bus Interface generates a START condition in Master mode. When this bit is cleared, a STOP condition is generated and the OPB IIC Bus Interface switches to Slave mode. When this bit is cleared by the hardware, because arbitration for the bus has been lost, a STOP condition is not generated.
30	Tx FIFO Reset	Transmit FIFO Reset. This bit must be set if arbitration is lost or if a transmit error occurs to flush the FIFO.
31	EN	OPB IIC Enable. This bit must be set before any other CR bits have any effect.

Status Register (SR)

This register contains the status of the OPB IIC Bus Interface. All bits are cleared upon reset. Table 4 provides a definition of the status register.

Table 4: Status Register Bit Definitions

Bit(s)	Name	Description
0 - 23	N/A	Reserved.
24	Tx_FIFO_Empty	Transmit FIFO empty. This bit is set High when the transmit FIFO is empty.
25	Rc_FIFO_Empty	Receive FIFO empty. This is set High when the receive FIFO is empty.
26	Rc_FIFO_Full	Receive FIFO full. This bit is set High when the receive FIFO is full. This bit is set only when all sixteen locations in the FIFO are full, regardless of the value written into Rc_FIFO_PIRQ.
27	Tx_FIFO_Full	Transmit FIFO full. This bit is set High when the transmit FIFO is full.
28	SRW	Slave Read/Write. When the IIC Bus Interface has been addressed as a Slave (AAS is set), this bit indicates the value of the read/write bit sent by the Master. This bit is only valid when a complete transfer has occurred and no other transfers have been initiated. A "1" indicates Master reading from Slave. A "0" indicates Master writing to Slave.
29	BB	Bus Busy. This bit indicates the status of the IIC bus. This bit is set when a START condition is detected and cleared when a STOP condition is detected.

Table 4: Status Register Bit Definitions (Contd)

Bit(s)	Name	Description
30	AAS	Addressed as Slave. When the address on the IIC bus matches the Slave address in the Address Register (ADR), the IIC Bus Interface is being addressed as a Slave and switches to Slave mode. If 10-bit addressing is selected this device will only respond to a 10-bit address or general call if enabled. This bit is cleared when a stop condition is detected or a repeated start occurs.
31	ABGC	Addressed By a General Call. This bit is set high when another master has issued a general call and the general call enable bit is set high, CR(1) = '1'.

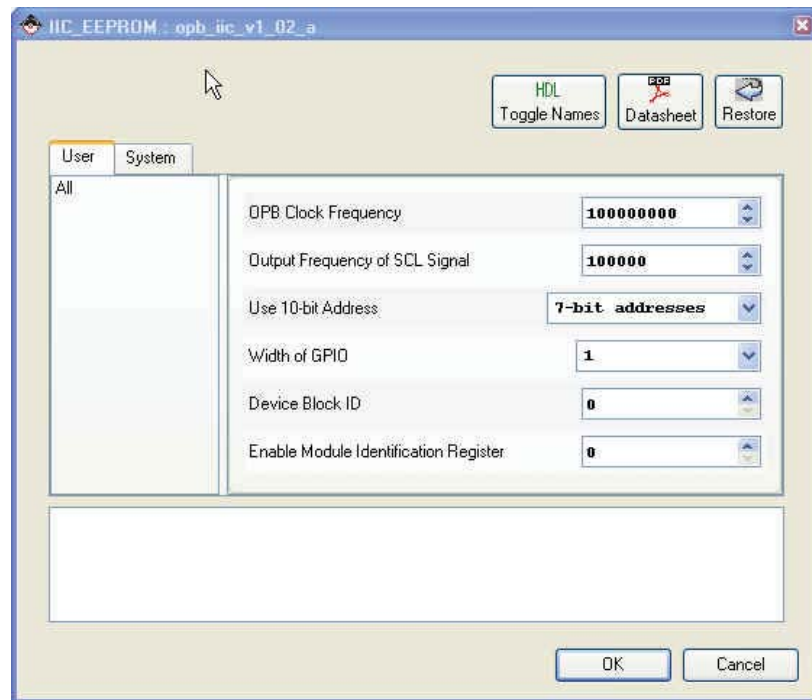

Table 5 provides a register description of the Interrupt Status register.

Table 5: Interrupt Status Register

Bit	Name	Description
24	TFHE	Transmit FIFO Half Empty
25	NAAS	Not Addressed as Slave
26	AAS	Addressed as Slave
27	BNB	Bus is not Busy
28	RFF	Receive FIFO Full
29	TFE	Transmit FIFO Empty
30	TE/STC	Transmit Error/Slave Transmit Complete
31	AL	Arbitration Lost

Configuring the OPB IIC Core

Figure 8 shows how to specify the values of IIC generics in EDK. To access the dialog box in the figure, double click on the OPB IIC core in the EDK System Assembly View..

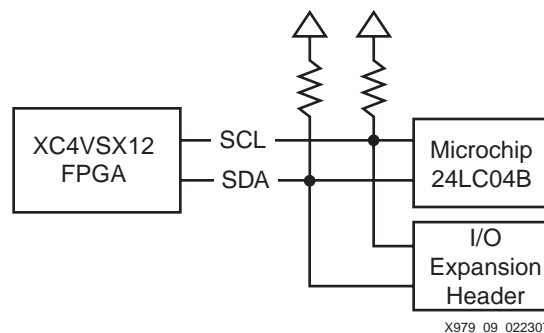

X979_08_012907

Figure 8: Specifying the Values of OPB IIC Generics in EDK

Microchip 24LC04

The Microchip Technology 24LC04B-I/ST with 4-KB EEPROM is provided on the ML403 board to store non-volatile data. The EEPROM write protect is tied off on the board to disable its hardware write protect. The IIC bus is extended to the expansion connector to allow additional devices to be added to the IIC bus.

Figure 9 shows IIC Bus Devices on the ML403.

X979_09_022307

Figure 9: ML403 IIC Bus

The 24LC04 is organized as two blocks of 256 bytes. It has a page write buffer of up to 16 bytes. The 24LC04 operates as an IIC slave. The 24LC04 accepts a control byte which contains control code, block select, and Read/Write fields shown in Figure 10. The control code

is '1010 for read and write operations. The A2, A1 bits are don't cares. The A0 bit is used by the master device to select which of the two 256-word blocks of memory are accessed. The 24LC04 write transactions are either a byte write or a page write. The page write begins the same as the byte write but instead of generating a stop condition the master transmits up to 16 data bytes to the 24LC04B. The 24LC04 supports current address, random, and sequential read operations.

Figure 10: 24LC04 Control Byte Allocation

ML403 Board Information

According to the MicroChip 24L024B data sheet, the ML403 board has a low-level output current (IOL) of 3.0 mA at a VCC of 2.5v. The ML403 boards are shipped in the configuration shown in Figure 11. The board must be modified for this design to work correctly. Replace the 10K Ohm R70 and R71 resistors with 833 or 1K Ohm resistors. See Answer Record 24049 for additional information.

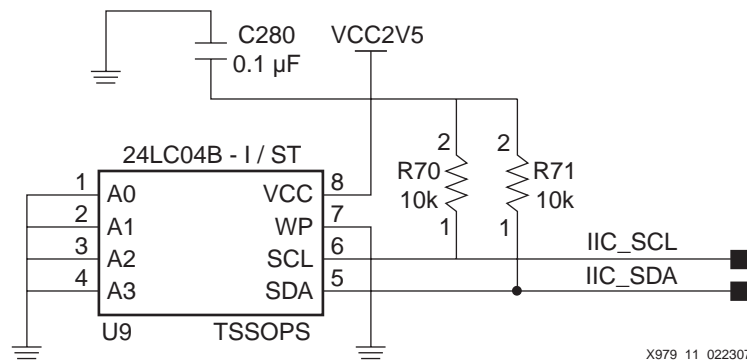

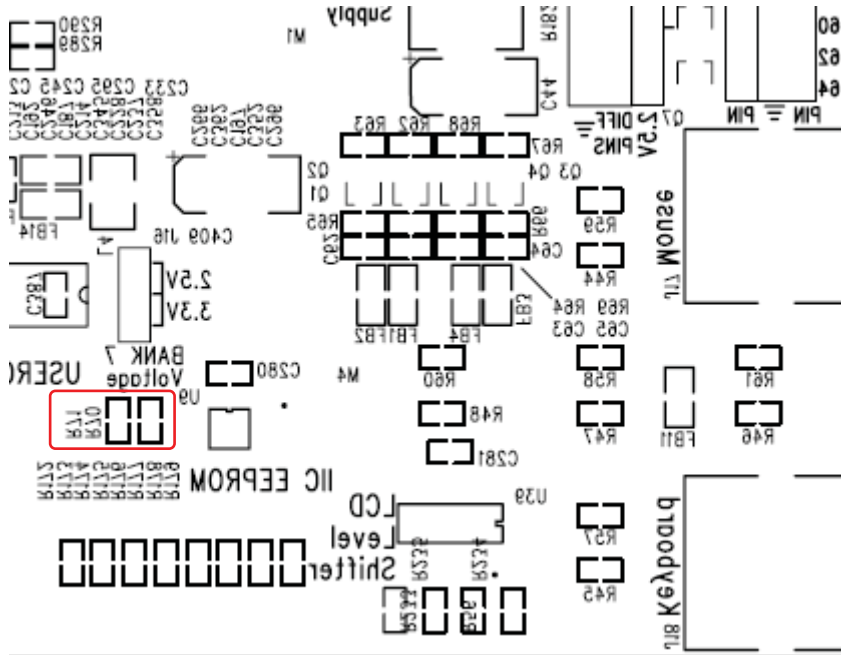

Figure 11: ML40x Schematic for IIC Connections

The resistors are located on the board as shown in Figure 12.

X979_12_022307

Figure 12: ML40x Resistors

If additional IIC devices are connected to the bus via the expansion header as shown in [Figure 13](#), insert additional pull-up resistors on the external signals connected at pins 31 and 32. The resistor values are dependent on the voltage.

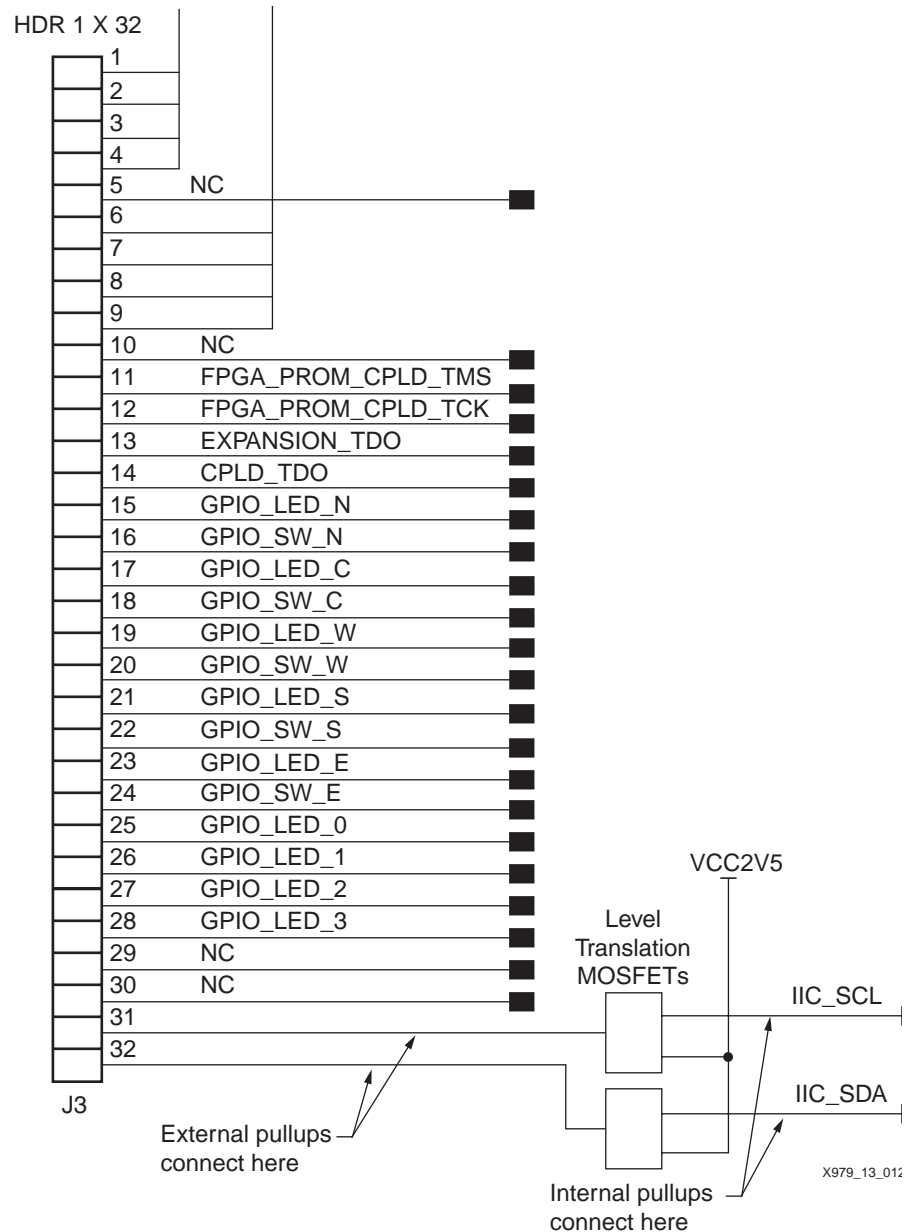

Figure 13: Expansion Header

Figure 14 shows the FPGA pins driving the IIC Bus.

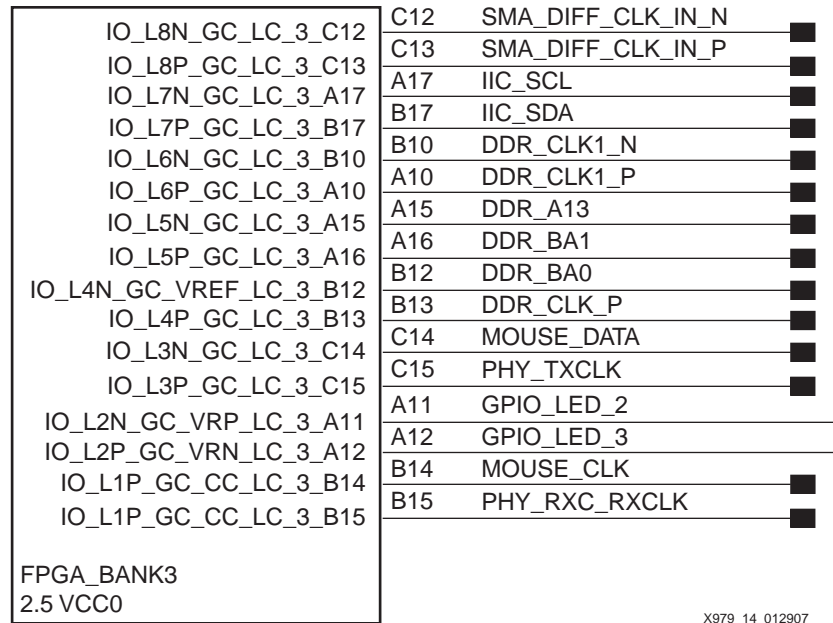

Figure 14: FPGA IIC Pins

TotalPhase Aardvark Adapter

In the reference design, the OPB IIC in the XC4VFX12 on the ML403 board interfaces to the IIC in the Aardvark Adapter. The Aardvark IIC/SPI Embedded Systems interface is a multi-functional host adapter. The Aardvark Control Center software interacts with the Aardvark Adapter. The Control Center controls the functionality of the Aardvark Adapter. It uses the Aardvark IIC/SPI Software API. The Aardvark Adapter has six functional modes. The IIC-related modes are the IIC + SPI and IIC Bus Monitoring modes.

The Aardvark must be configured for use before the Aardvark Control Center software can be used to send and receive messages. Configuring the Aardvark Adapter binds the instance of the application with the available unit until the adapter is disconnected or the application is terminated.

The Configure Aardvark Adapter window is organized into two major sections: list of available adapters connected to the computer and list of the six operational modes. The main application window is divided into two sections. The top section contains the modules used with the Aardvark Adapter. The bottom section contains the transaction log which tracks all transactions that the Aardvark sends or receives. The transaction log contains the time, read or write transaction, master or slave, bit rate, address, number of bytes, and data.

Figure 15 shows the Aardvark Control Center GUI.

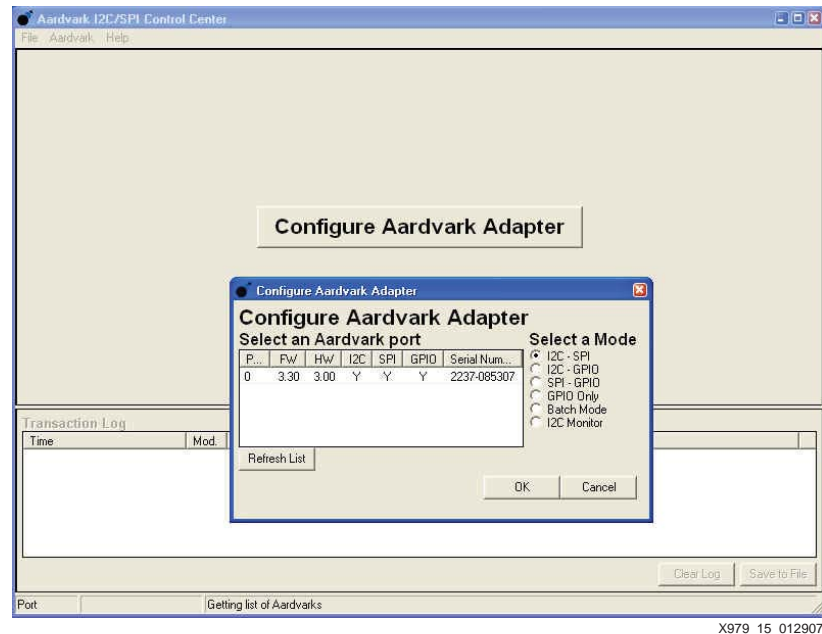

Figure 15: Aardvark Control Center

Interfacing to the OPB IIC on the ML403 Board to the Aardvark Adapter

Figure 16 shows the principle interface blocks when transferring data between the OPB IIC in the XC4VFX12 on the ML403 board and the IIC in the Aardvark Adapter.

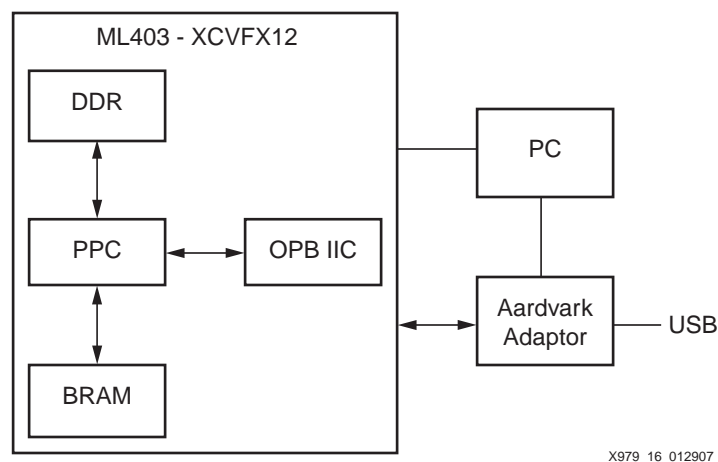

Figure 16: Interfacing ML403 Board OPB IIC with the Aardvark Adapter

Executing the Reference System using the Pre-Built Bitstream and the Compiled Software Applications

To execute the system using files inside the `m1403_ppc_opb_iic/ready_for_download` directory, follow these steps:

1. Change to the `m1403_ppc_opb_iic/ready_for_download` directory.
2. Use `iMPACT` to download the bitstream by using the following:
`impact -batch xapp.cmd`

3. Invoke XMD and connect to the MicroBlaze processor by the following command:
`xmd -opt xapp.opt`
4. Download the executable by the following command
`dow <path>/executable.elf`

Executing the Reference System from EDK

To execute the system using EDK, follow these steps:

1. Open `system.xmp` inside EDK.
2. Use **Hardware** → **Generate Bitstream** to generate a bitstream
3. Download the bitstream to the board using **Device Configuration** → **Download Bitstream**.
4. Invoke XMD with Debug Launch XMD.
5. Download the executable by the following command.
`dow <path>/executable.elf`

Verifying the Reference Design with Xilinx Microprocessor Debugger

After downloading the bitstream file, issue the following XMD commands to verify that the ML403 reference design is set up correctly.

```
mr d 0x42600100 8
```

The expected value of the control register after a reset, located at 0x42600100 is 0x00000000. The expected value of the status register, located at 0x42600104, is 0x000000C0. The reset values of the Transmit and Receive FIFO registers are indeterminate. The reset values of the Transmit and Receive FIFO Occupancy and the Address registers is 0.

Except for the Status, , Receive FIFO, and Transmit and Receive Occupancy registers, all registers are writeable.

```
mwr 0x42600100 0xFFFFFFFF
```

```
mr d 0x42600100 1
```

Using XMD commands, verify that the OPB IIC registers can be written and read as defined in Tables 2-5.

Software Projects

The reference system contains the following software projects. In each software project directory, there is a `src` sub-directory for the source code. The connections in [Figure 9](#) are used for the `eeeprom`, `low_level_eeeprom`, `dynamic_eeeprom`, and `low_level_dynamic_eeeprom` projects. These projects interface to the 24LC04. The connections in [Figure 3](#) are used for the `mult_master` and `repeated_start` project. These projects interface to the IIC Bus via the Aardvark Adapter.

Projects interfacing to Microchip 24LC04

eeeprom: This project transmits and receives data using the high level (L1) software driver. The OPB IIC is the master and the 24LC04 is configured as the slave. The OPB IIC master writes data into the 24LC04 and reads it back.

low_level_eeeprom: This project transmits and receives data using the low level (L0) software driver. The OPB IIC is the master and the 24LC04 is configured as the slave. The OPB IIC master writes data into the 24LC04 and reads it back. This is a polled mode example.

dynamic_eeeprom: This project transmits and receives data using the high level (L1) software driver. The OPB IIC is the master and the 24LC04 is configured as the slave. The OPB IIC master writes data into the 24LC04 and reads it back.

low_level_dynamic_eeprom: This project transmits and receives data using the low level (L0) software driver. The OPB IIC is the master and the 24LC04 is configured as the slave. The OPB IIC master writes data into the 24LC04 and reads it back. This is a polled mode example.c

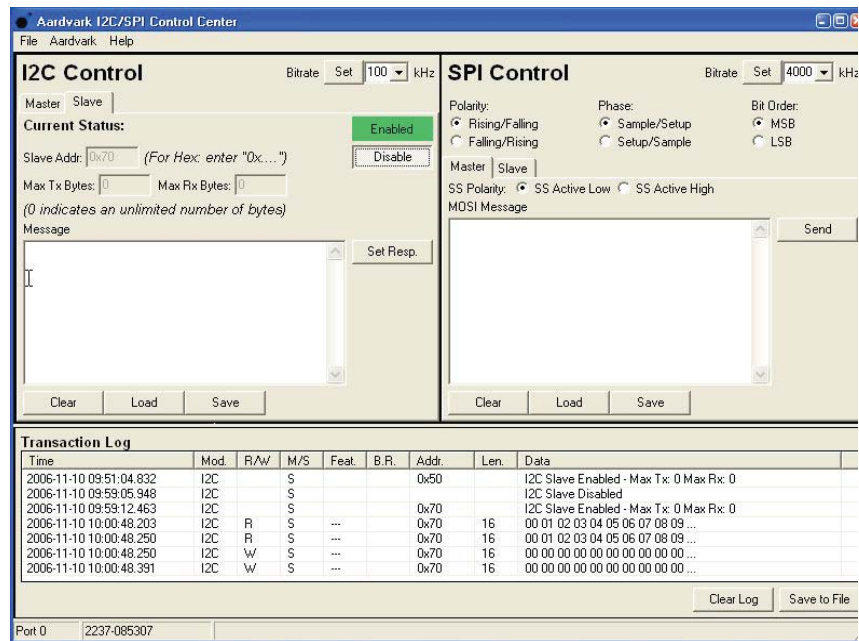

Projects interfacing to Aardvark Adapter

multi_master: This project transmits and receives data using the high level (L1) software driver. The OPB IIC is an IIC master and the IIC in the Aardvark is a master. The Microchip 24LC04B is configured as a IIC slave. The WP pin of the 24LC04 is hardwired to ground on the ML403. The interrupt mode is used. The IIC master in the Aardvark Adapter writes the data to the MicroChip 24LC04B with the No Stop option enabled. Any attempts to write data from the OPB IIC master results in a Bus Busy status. The Aardvark Adapter releases the bus by executing the FREE BUS command. When the bus is free, the OPB IIC master initiates a bus transaction.

repeated_start: This project transmits and receives the data using the high level (L1) driver. The IIC devices on the ML300/ML310/ML410 boards do not support the repeated start option. The ML403 OPB IIC is configured as a master and the Aardvark Adapter IIC is configured as a IIC slave. The OPB IIC writes the data to the Aardvark IIC in multiple transactions with the repeated start option enabled. The external IIC device slave address is a 7 bit address defined by SLAVE_ADDRESS. The number of bytes sent and received is defined by SEND_COUNT and RECEIVE_COUNT.

Figure 17 shows the repeated start example.

Specify 0x70 as the Address. The SPI Control is not used. The transaction log shows 16 write and 16 read transactions at address 70.

X979_17_012907

Figure 17: Repeated Start Example

slave: This project transmits and receives the data using the high level (L1) driver. The ML403 OPB IIC is configured as a slave and the Aardvark Adapter IIC is configured as a IIC master. The Aardvark Adapter IIC writes the data in test_data to the OPB IIC and reads it back.

Figure 18 shows the slave example. The message is in transmit.txt, and is the sentence "Lester was here.". The transaction log matches the message. The address is 0x70. Click **Master Write** to generate the transaction.

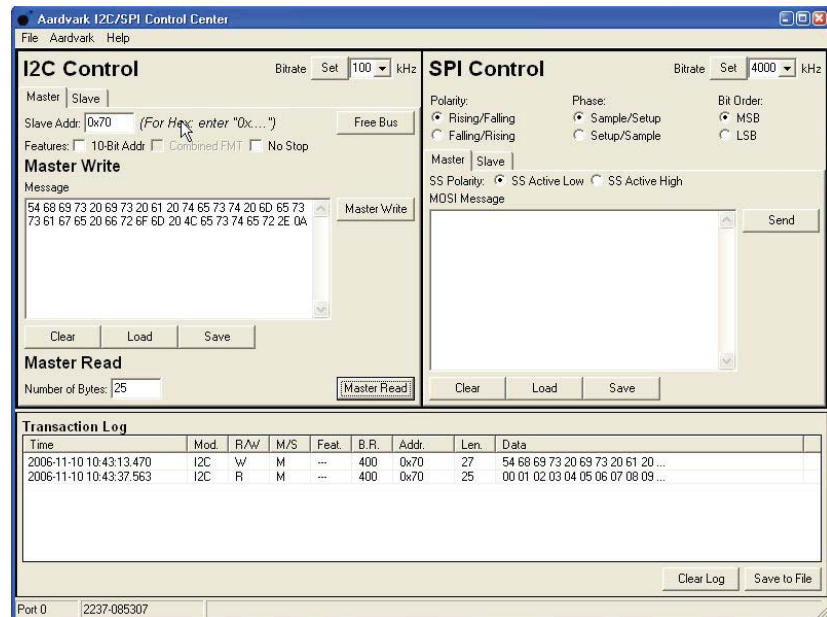

Figure 18: Slave Example

Running the Applications

In XPS, select the **Applications** tab under the Project Information Area to view the **Software Project**.

Figure 19 shows the structure of the `dynamic_eeprom` project. Make the `dynamic_eeprom` project active and the remaining software projects inactive.

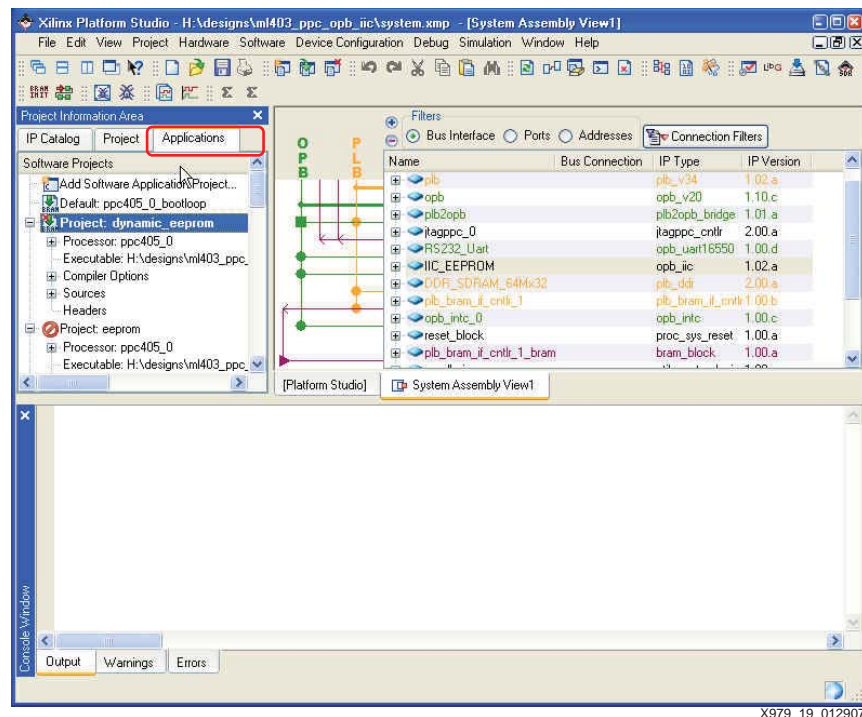

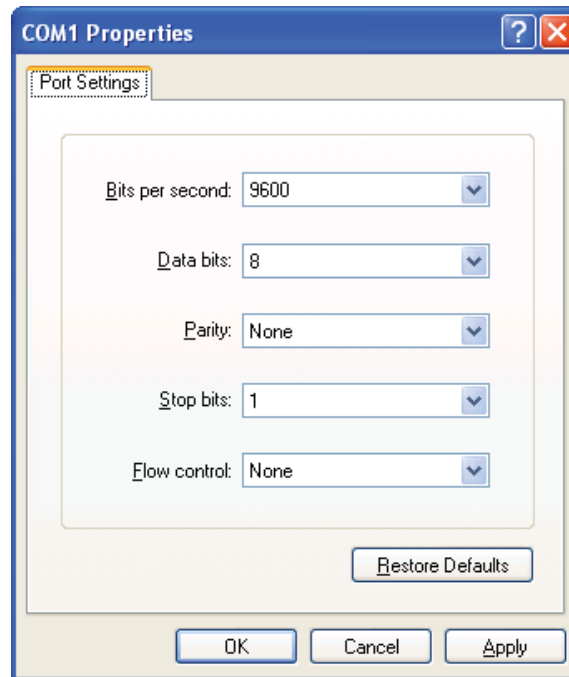

Figure 19: Selecting the eeprom Software Project

Select **dynamic_eeprom** and right click to build the project. If more than one software project is used, make the unused software projects inactive.

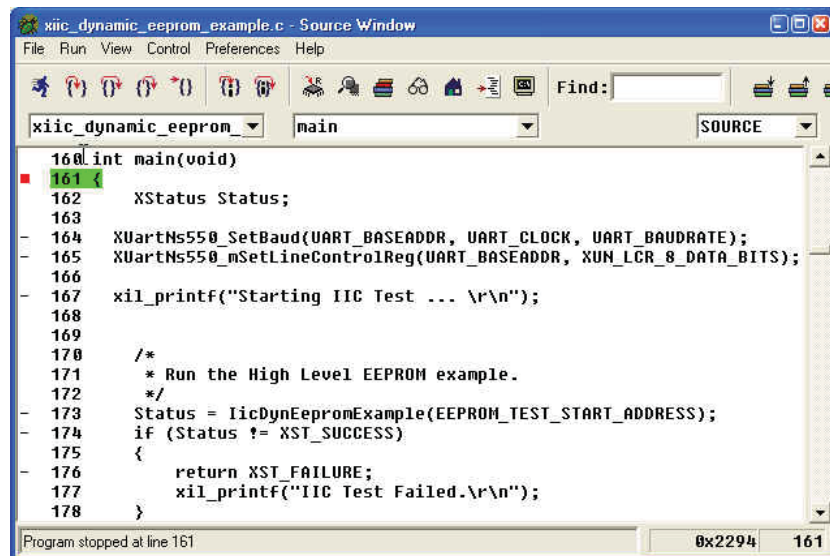

Connect a serial cable to the RS232C port on the ML403 board. Start up a HyperTerminal. Set Bits per second to **9600**, Data bits to **8**, Parity to **None**, and Flow Control to **None**, as shown in Figure 20.

X979_20_012907

Figure 20: HyperTerminal Parameters

From XPS, start XMD and enter **rst**. Invoke GDB and select **Run** to start the application as shown in Figure 21. The `eeprom.c` code written for the ML403 shown in the figure runs without any modifications on this reference system.

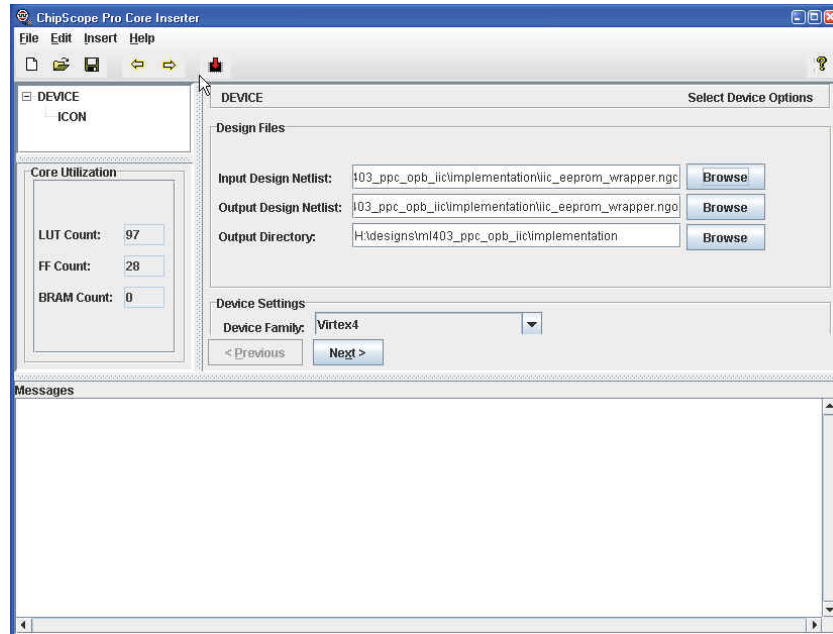

X979_21_012907

Figure 21: Running dynamic_eeprom in GDB

Using ChipScope with OPB IIC

To facilitate the use of ChipScope to analyze OPB IIC hardware, the `iic.cdc` file is included in the `m1403_ppc_opb_iic/chipscope` directory. The `iic.cdc` is used to insert a ChipScope ILA core into the `opb_iic` core. The following steps are used to insert a core and analyze OPB IIC problems with ChipScope.

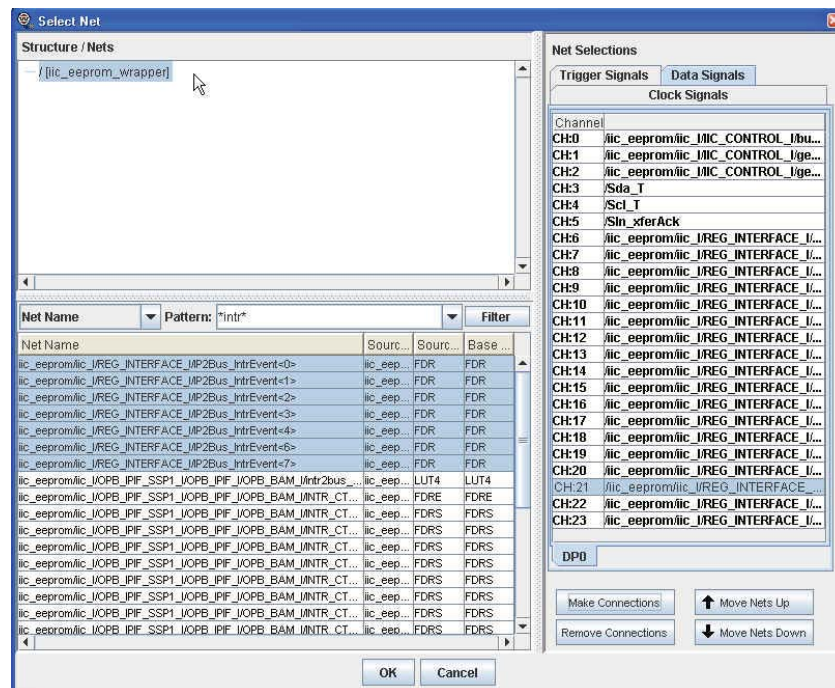

1. Invoke XPS. **Run Hardware** → **Generate Netlist**.
2. In the `iic.cdc` file, change the path `<design_directory>` name to the directory in which the design files are installed. Three paths need to be changed.
3. Run **Start** → **Programs** → **ChipScope Pro** → **ChipScope Inserter**
4. From ChipScope Inserter, run **File** → **Open Project ii.cdc**. Figure 22 shows the ChipScope Inserter setup GUI.

X979_22_012907

Figure 22: ChipScope Inserter Setup

5. Figure 23 shows the GUI for making net connections. Click **Next** to move to the **Modify Connections** window. If there are any red data or trigger signals, correct them. The **Filter Pattern** can be used to find net(s). As an example of using the **Filter Pattern**, enter `intr` in the dialog box to locate interrupt signals. In the **Net Selections** area, select either **Clock**, **Trigger**, or **Data Signals**. Select the net and click **Make Connections**.

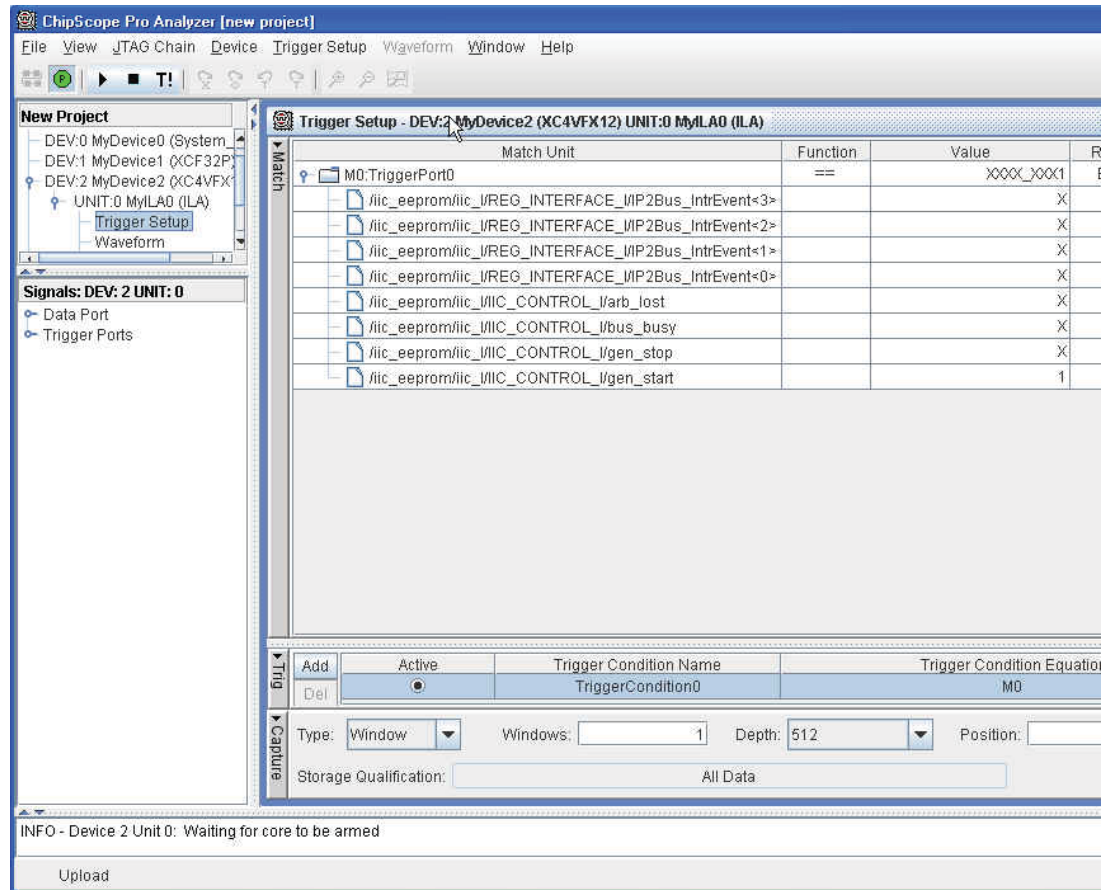

X979_23_012907

Figure 23: Making Net Connections in ChipScope Inserter

7. Click **Insert Core** to insert the core into `iic_eeprom_wrapper.ngo`. In the `ml403_ppc_opb_IIC/implementation` directory, copy `iic_eeprom_wrapper.ngo` to `iic_eeprom_wrapper.ngc`.
8. In XPS, run **Hardware** → **Generate Bitstream and Device Configuration** → **Download Bitstream**. Do not rerun **Hardware** → **Generate Netlist**, as this overwrites the `implementation/iic_eeprom_wrapper.ngc` produced by the step above. Verify that the file size of the `opb_iic_wrapper.ngc` with the inserted core is significantly larger than the original version.
9. Invoke ChipScope Pro Core Analyzer by selecting **Start** → **Programs** → **ChipScope Pro** → **ChipScope Pro Analyzer**
Click on the JTAG chain icon located at the top left of Analyzer GUI. Verify that the message in the transcript window indicates that an ChipScope ICON is found.
10. The ChipScope Analyzer waveform viewer displays signals named `DATA*`. To replace the `DATA*` signal names with the signal names specified in ChipScope Inserter, select **File** → **Import** and enter `iic.cdc` in the dialog box.

The waveform viewer is more readable when buses rather than discrete signals are displayed. The Reverse Bus Order operation below Add to Bus in the figure can be useful in analyzing ChipScope results.

X979_24_022307

Figure 24: Setting Up the Chipscope Trigger

11. Set the trigger in the Trigger Setup window. The trigger used depends on the problem being debugged. Change the **Windows to N samples** to a setting of **100**. Arm the trigger by selecting **Trigger Setup** → **Arm**, or clicking on the **Arm** icon.

As shown in Figure 24, the trigger setup is to trigger when `gen_start` is High.

12. Run **XMD** and/or **GDB** to activate the trigger patterns which cause ChipScope to display meaningful output.

13. ChipScope results are analyzed in the waveform window as shown in Figure 25. The waveforms may be easier to read if the discrete signals are removed after they are renamed. To share the results with remote colleagues, save the results in the waveform window as a Value Change Dump (vcd) file. The vcd files can be translated and viewed in most simulators. The `vcd2wlf` translator in Modeltech reads a vcd file and generates a wlf file for viewing in the Modeltech waveform viewer. The vcd file can be opened in the Cadence Design System, Inc. Simvision design tool by selecting **File** → **Open Database**.

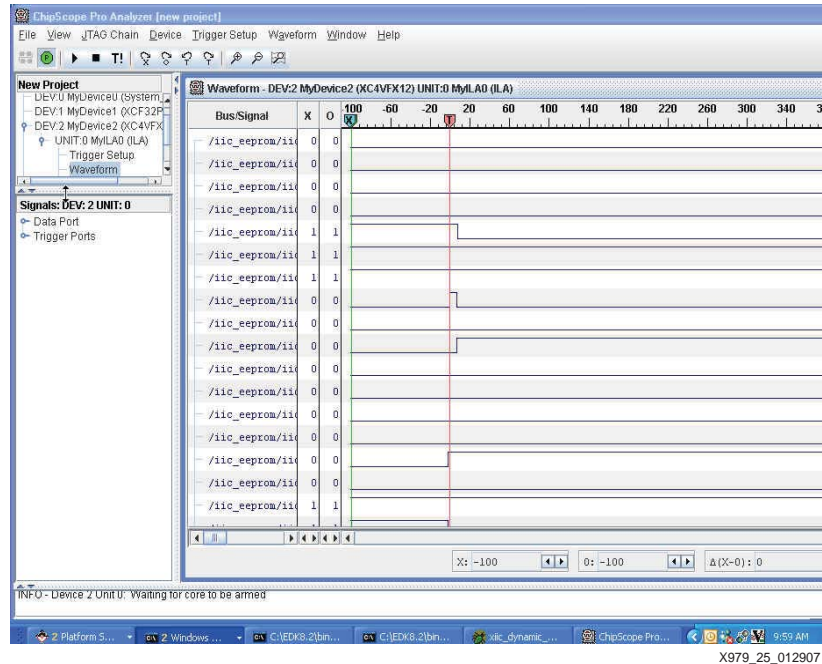

Figure 25: ChipScope Analyzer Results

Linux Kernel

New users of MontaVista Linux should read XAPP 765 Getting Started with EDK and Monta Vista Linux. The steps to build and boot a Linux kernel are given below. Steps 1-3, 7, 8 are run on a Linux machine with MontaVista Professional Edition© installed.

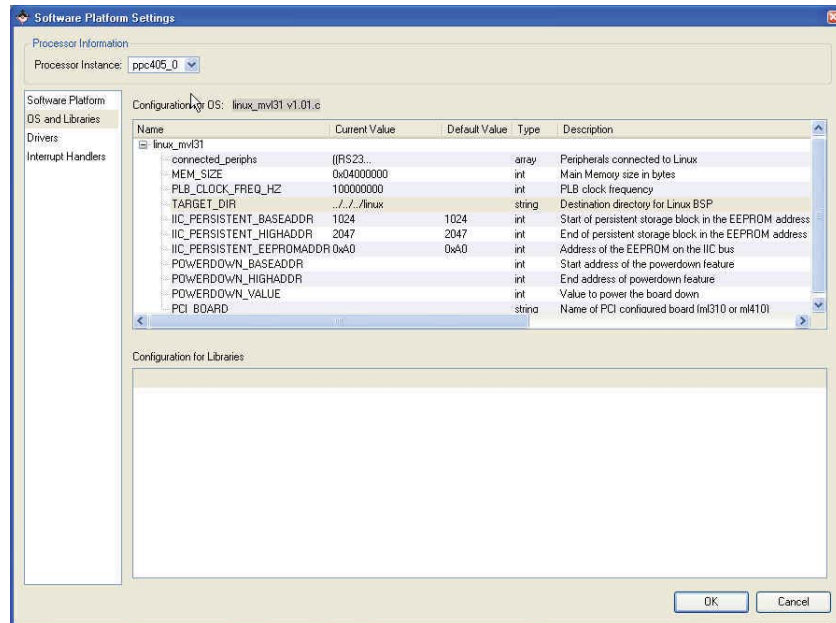

1. Add `/opt/montavista/pro/host/bin` and `/opt/montavista/pro/devkit/ppc/405/bin` to `$PATH`.

2. Change to the `m1403_IIC/linux` directory.
3. Run

```
tar cf - -C /opt/montavista/pro/devkit/lsp/xilinx-m1300-ppc_405/linux-2.4.20_mv131/ . tar xf -
```

4. To generate the Linux LSP in XPS, enter **Software** → **Software Platform Settings**. Select **Kernel and Operating Systems**, then select **linux_mv131 v1.00.c**.

5. Under **OS and Libraries**, set the entries as shown in Figure 26.

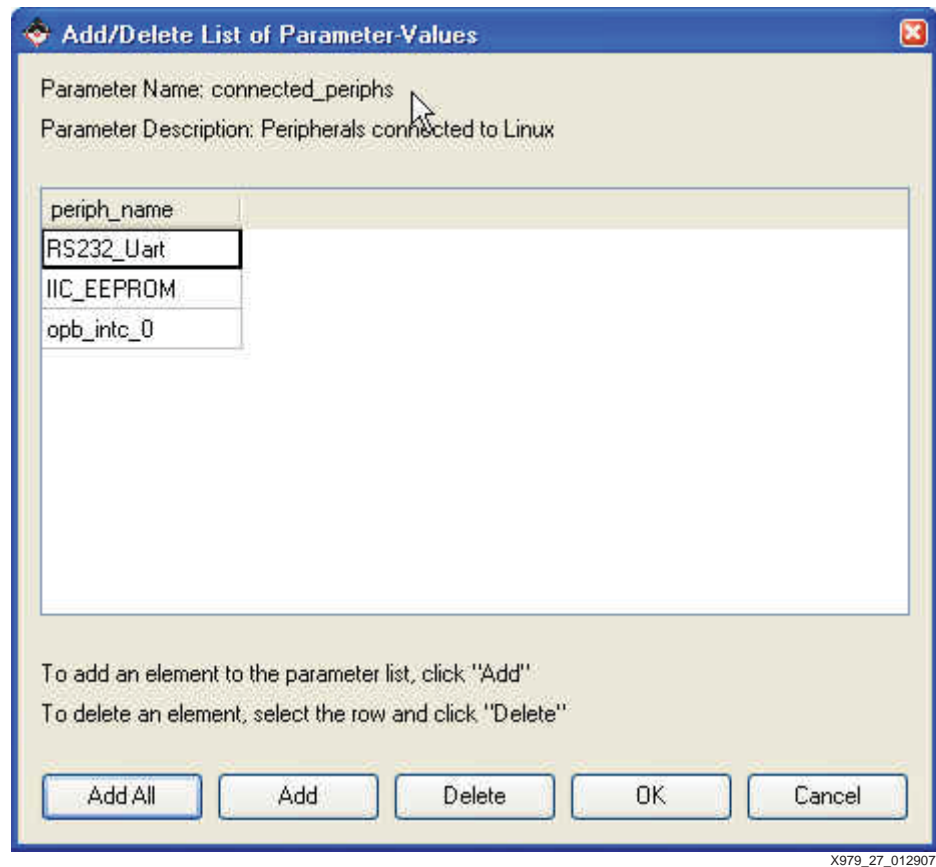

X979_26_012907

Figure 26: **BSP Settings**

Verify that the target directory is the same as the directory containing the Linux source.

- Click **Connect Periphs** and add the OPB_INTC, OPB_SYSACE, OPB_IIC, OPB_SPI, OPB_IIC, and OPB 16550 peripherals, using the instance names shown in Figure 27.

X979_27_012907

Figure 27: Connected Peripherals

Click **OK**.

- Select **Software** → **Generate Libraries and BSPs** to generate the LSP in `ml403_ppc_opb_iic/linux`.
- From `ml403_ppc_opb_iic/linux`, run `patch_nobspgen`.
- The `ml403_ppc_opb_iic/linux/.config` is used to define the contents of the Linux kernel. Run

```
make oldconfig
```

An alternative is to enter **make menuconfig** and generate a new `.config` using the following options.

- Select General Setup
 - Enable IIC. Disable PS/2 keyboard. Change to `/dev/ram` for booting from ramdisk.
 - Select Input Core Support. Disable all.
 - Select Character Devices. Disable Virtual. Leave Serial enabled. Disable Xilinx GPIO and Touchscreen.
- Run **make clean dep zImage.initrd**. Verify that the `zImage.initrd.elf` file is in the `ml403_ppc_opb_iic/linux/arch/ppc/boot/images` directory.
 - Invoke **Impact** and download **implementation/download.bit** to XC4VFX12. Either select **Device Configuration** → **Download Bitstream** from XPS or run the following

command from the command prompt:

```
impact -batch etc/download.cmd
```

12. Invoke XMD. From the `ml403_ppc_opb_iic/linux` directory, enter the following commands in the XMD window.

```
rst  
dow arch/ppc/boot/images/zImage.initrd.elf  
con
```

13. View the output in the HyperTerminal window. Login as `root`. Enter `cd /` and `ls -l` to view the contents of the mounted Linux partition.

14. An alternative to downloading the Linux kernel executable is to load it into CompactFlash. The file used uses an ace file extension. To generate an ace file, run the command below from the `ml403_ppc_opb_iic` directory.

```
xmd -tcl /genace.tcl -jprog -hw ./implementation/system.bit -ace  
./implementation/ace_system_hw.ace -board ML403
```

Copy the ace file to a 64-512 MB CompactFlash (CF) card in a CompactFlash reader/writer. Remove the CF card from the CF reader/writer and insert it into the CompactFlash slot (J22) on the ML403 board. Power up the board.

Simulation

The `ml403_ppc_opb_iic/simulation` directory contains waveform log file, `opb_iic.wlf`, for IIC transactions discussed in this section.

The `opb_iic.wlf` files are easily loaded into the Modeltech simulator using the **File** → **Open** command, specifying the `*.wlf` file type.

The OPB IIC core has two Finite State Machine (FSM). The clock FSM has IDLE, START, SCL_LOW_EDGE, SCL_LOW, SCL_HIGH_EDGE, SCL_HIGH, STOP_WAIT states. The main FSM has IDLE, HEADER, ACK_HEADER, RCV_DATA, XMIT_DATA, ACK_DATA, and WAIT_ACK states.

Figure 28 shows the two OPB IIC cores in the simulation. The simulation is a Bus Functional Model simulation of two OPB IIC cores. The IIC cores with addresses 20 and AA are designated `iic_20` and `iic_AA`, with `C_BASEADDR` of `0xE0000000` and `0xE1000000`, respectively. Both cores connect to SCL and SDA. The stimuli is provided by writing the OPB IIC registers.

As an example

```
write cr 41
```

enables the OPB IIC and sets the General Call enable. The address determines which OPB IIC is the target of the write, with `0xE0000100` for `iic_20` and `0xE1000100` for `iic_AA`. It may be useful to consult the register map in Table 2 and the control (Table 3), status (Table 4), and interrupt status register (Table 5) definitions.

In most cases, after data is transmitted, the test waits for an interrupt from the OPB IIC.

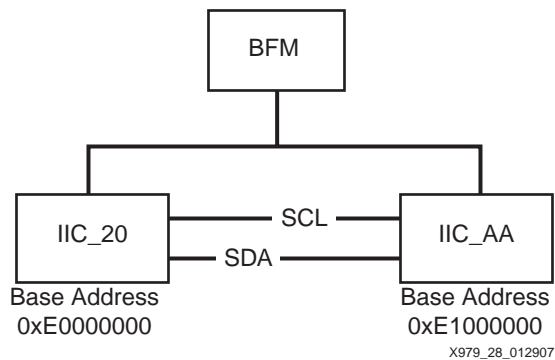

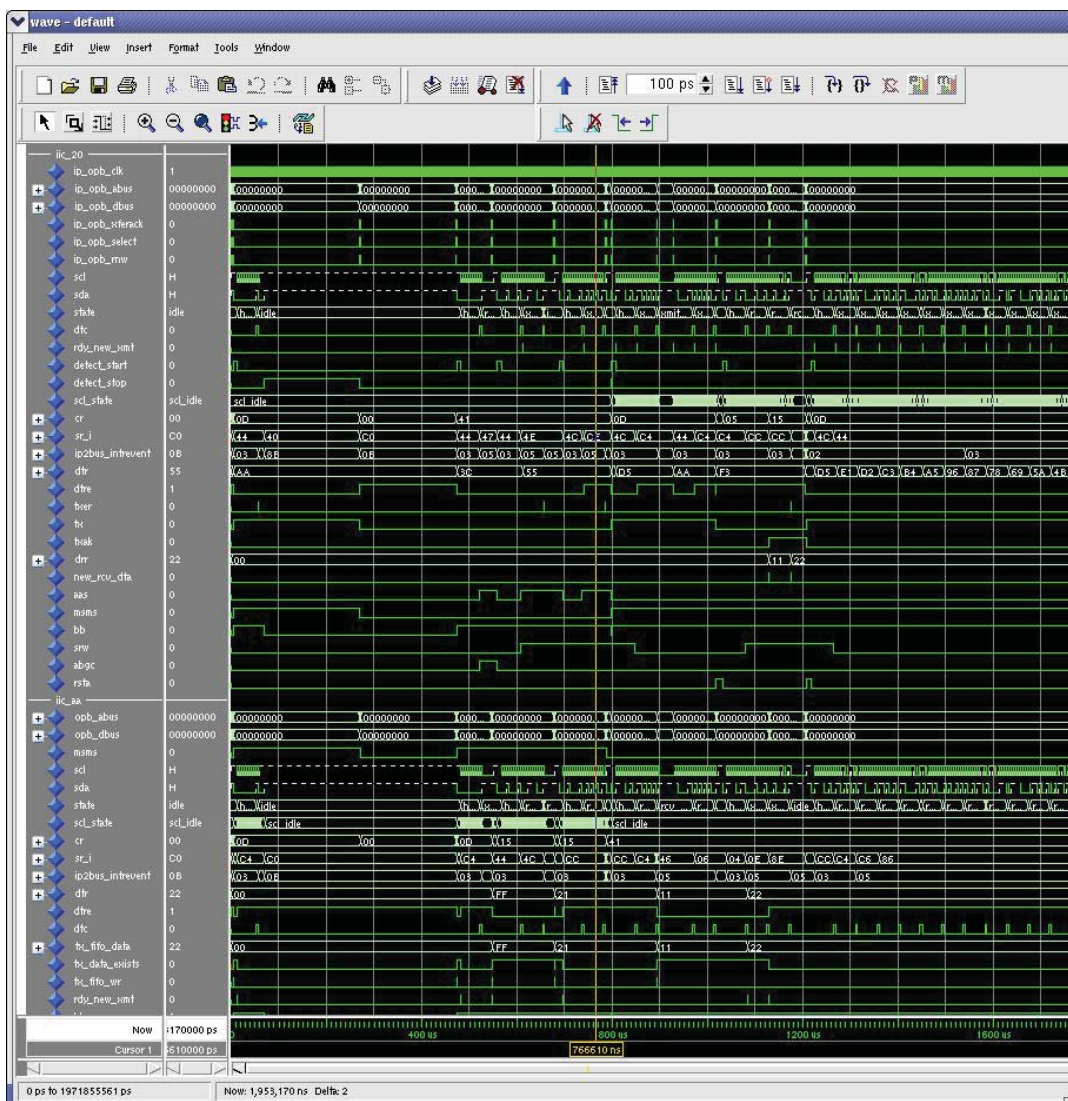

Figure 28: OPB IIC Simulation

Internal signal names used in the OPB IIC core are provided in Table 6.

Table 6: Internal Signals in OPB IIC

Signal Name	Functionality
Txak	Transmit acknowledge
Gc_en	General call address enable
Ro_prev	Receive overrun prevent
Dtre	Data transmit register empty
Msms	Master/Slave select
Dtr(7:0)	Data Transmit Register
Adr(7:0)	IIC Slave Address Register
Ten_adr(7:5)	10-bit Slave Address Register
Bb	Bus Busy
Aas	Addressed as slave
Al	Arbitration lost
Srw	Slave read/write
Abgc	Addressed by general call
Data_iic(7:0)	IIC data for microprocessor
New_rcv_data	New data received on IIC bus
Tx_under_prev	Transmit FIFO Empty IRQs
slave_sda	SDA value when slave
master_sda	SDA value when master
sm_stop	Stop condition needs to be generated
rsta_tx_under_prev	Repeated start Tx underflow prevent

The simulation runs for 2000 ns as shown in Figure 29. There are 3 sections in the simulation, shown in the following figures.

X979_29_022307

Figure 29: Complete Simulation

Figure 31 provides the Arbitration Lost test code. This pseudo-code can be tracked in the simulation.

```
write ADR_20 0x20
write CR_20 40
write CR_AA 0x01
write ADR_AA AA
write IER_AA 0x04
write RC_FIFO_PIRQ_20 0x0
write DTR_AA 0x0
write CR_AA 0x0D -- Enables AA as master (5.9us)
write IPIER_20 0x01
write DTR_20 AA
write CR_20 0x0D -- Enables 20 as master
wait_for_intr(30)
read IPISR 0xD3 -- Arbitration lost (260 us)
write CR_20 0x01 -- Clears interrupt
```

X979_31_012907

Figure 31: Arbitration Lost Test Code

The second test, shown in Figure 32, runs from 575 s to 790 s. This master, AA, receives 3C and 55 from 20. The following stimuli / results is seen in the opb_iic.wlf file.

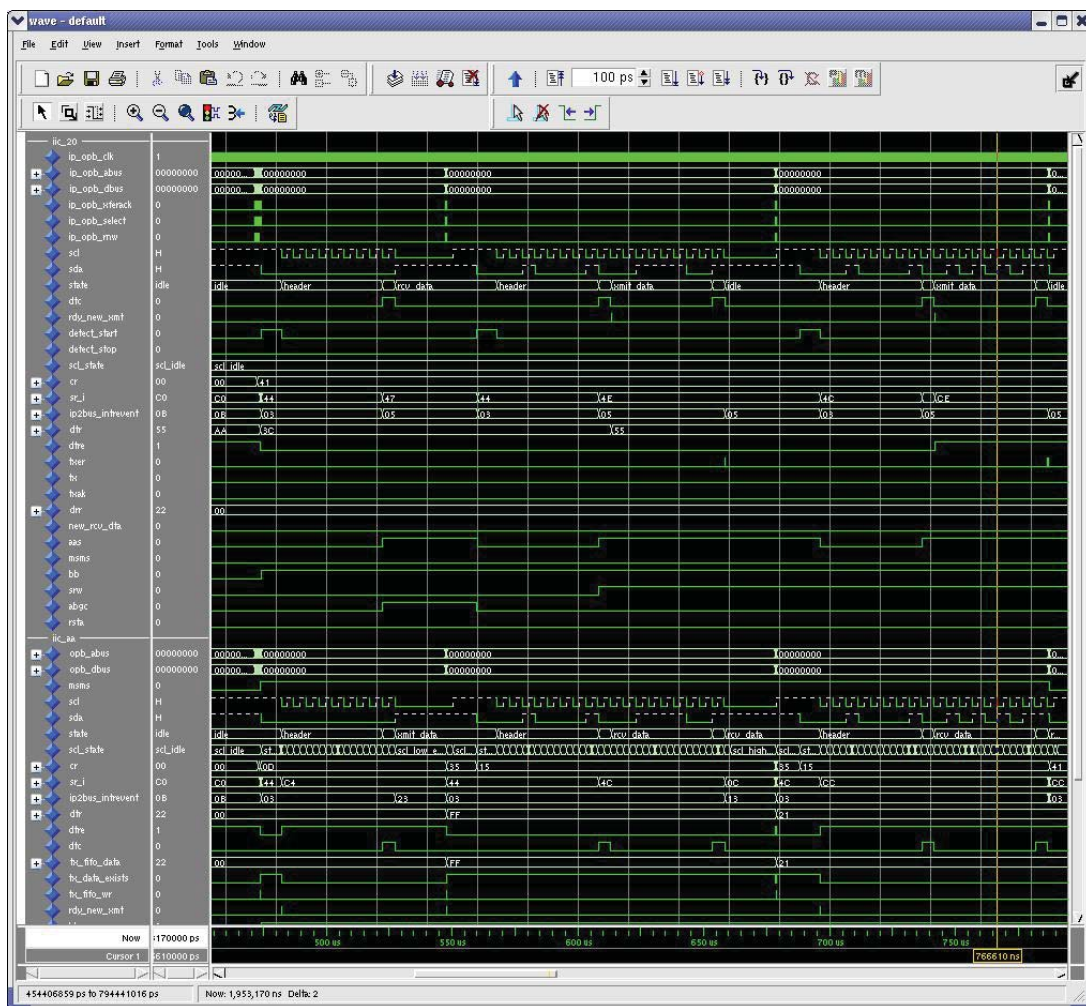

Figure 32: Simulation with iic_AA as Master

X979_32_022307

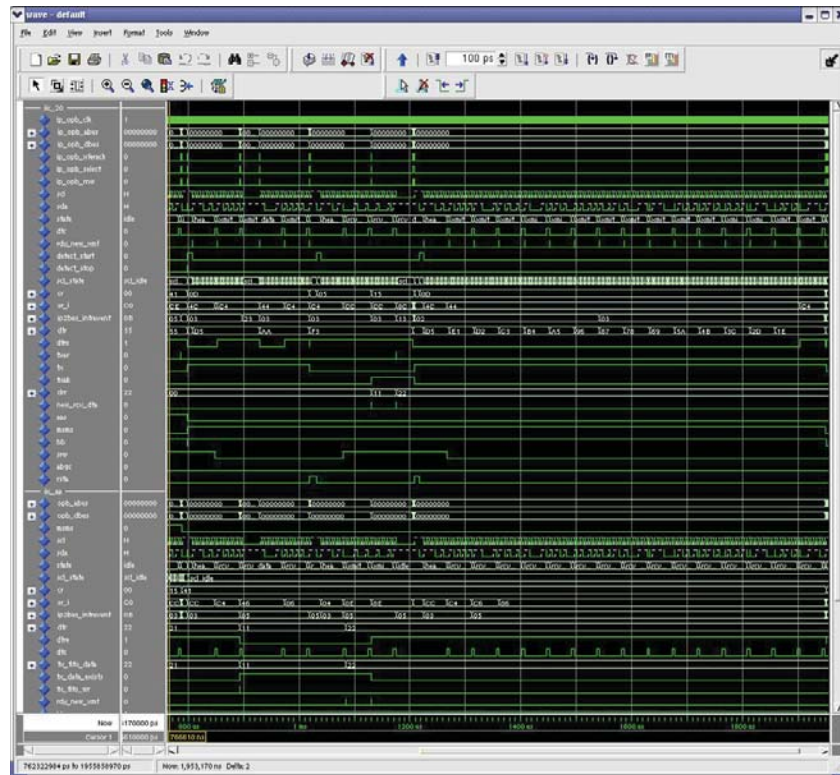

Figure 33 provides the test code used in the simulation with the OPB IIC with the AA address as the master.

```
write CR_20 0x40 -- GC, En
write ADR_20 0x20 - Sets address as 0x20
write CR_AA 0x01 - Enable
write ADR_AA 0xAA
write RC_FIFO_PIRQ_AA 0x0
write IER_AA 0x04 -- Enable DTRE interrupt
write RC_FIFO_PIRQ 0x01 (473 us)
write DTR_20 0x3C
write DTR_20 0x55
write DTR_AA 0x0 -- General Call
write CR_AA 0x0D -- RSTA, TxAK, TX, MSMS, Enable
wait_for_intr
read SR_AA 0xC4 -- TFE, RFE, BB
read ISR_AA 0xD4 -- TFHE, DTRE
write CR_AA 0x35 RSTA, MS, EN (547 us)
write DTR_AA 0x21
write DTR_AA 0xFF
write IER_AA 0x08
wait_for_intr -- waiting for DRR_AA full
read SR_AA 0x0C -- SRW, BB (678 us)
write CR_AA 0x37 -- Clear FIFO
write CR_AA 0x35
read DRR_AA 0x3C
write ISR_AA 0xC*
write DTR_AA 0x21
wait_for_intr
read SR_AA 0x8C
read ISR_AA 0xCA -- TXER, DFF Full
write CR_AA 0x41
read DRR_AA 0x55 (787 us)
write ISR_AA 0xC8
write IRE_AA 0x10 -- Enable Bus is not Busy
wait_for_intr
```

X979_33_012907

Figure 33: Test code with iic_AA as Master

Figure 34 shows the third test shown in `opb_iic.wlf`, run from 800 - 2000 us. IIC_20 is the master writing to IIC_AA, which is a 10-bit slave.

X979_34_012907

Figure 34: Simulation with `iic_AA` as Master

Figure 35 provides the test code for simulation with IIC_AA as master.

```

write DTR_20 0xF2
write DTR_20 0xD5
read TX_FIFO_OCY 0x01
write CR_20 0x0D -- Tx, MS, En
write RC_FIFO_PIRQ 0x01
write IER_AA 0x20 -- Enable AAS
wait_for_intr
read SR_AA C6 -- TFE, RFE, BB, AAS (893 us)
write DTR_AA 0x11
write DTR_AA 0x22
write IER_AA 0x47
read ISR_AA 0xA0 -- TFE, FFF
read SR_20 C4 -- TFE, RFE, BB
write IER_20 0x3F -- Enable DTRE
wait_for_intr -- DTRE occurs, D5 sent, and
throttle for 1500 ns
write DTR_20 0xC3 (928 us)
write DTR_AA AA
wait_for_intr -- DTRE occurs, C3, AA sent, and
throttle for 1500 ns
write CR 0x25 -- RSTA, Master Receive, MS, Enable
write DTR_20 0xF3
read DRR_20 0xC3
wait_for_intr -- DRR full occurred, repeated start,
F3 sent on bus
read ISR_20 0xCC -- RFF (1130 us)
read DRR_20 0x11 -- No Ack Master Receive
write CR_20 0x15
write ISR_20 0xCC
write IER_20 0x3B
wait_for_intr -- DRR full, 0x22 received, throttle
for 1500 ns
